## Lab 2: Bayesian Linear Regression

In this lab, we use Bayesian regression to fit a linear model. Consider a linear model of the form

$$z = a_1x + a_0 + w, \quad (1)$$

where  $x$  is the scale input variable, and  $\mathbf{a} = (a_0, a_1)^T$  is the vector-valued parameter with unknown entries  $a_0$ ,  $a_1$ , and  $w$  is the additive Gaussian noise:

$$w \sim \mathcal{N}(0, \sigma^2), \quad (2)$$

where  $\sigma^2$  is a known parameter.

Suppose that we have access to a training data set containing  $N$  samples  $\{x_1, z_1\}, \{x_2, z_2\}, \dots, \{x_N, z_N\}$ . We aim to estimate the parameter  $\mathbf{a}$  by finding its posterior distribution. When the training finishes, we make predictions based on new inputs. We consider a Bayesian approach, which models the parameter  $\mathbf{a}$  as a zero mean isotropic Gaussian random vector whose probability distribution is expressed as

$$p(\mathbf{a}) = \mathcal{N}\left(\begin{bmatrix} 0 \\ 0 \end{bmatrix}, \begin{bmatrix} \beta & 0 \\ 0 & \beta \end{bmatrix}\right), \quad (3)$$

where  $\beta$  is a known hyperparameter.

Download `reg.zip` under Files/Labs/Lab2 Part1/ on Quercus and unzip the file. File `training.txt` contains the training data: the first column is the inputs; the second column is the targets. The training data is generated from  $z = -0.5x - 0.1 + w$ . Please answer the questions below and complete `regression.py`. File `util.py` contains a few useful functions.

### Questions

1. Express the posterior distribution  $p(\mathbf{a}|x_1, z_1, \dots, x_N, z_N)$  using  $\sigma^2, \beta, x_1, z_1, x_2, z_2, \dots, x_N, z_N$ .
2. Let  $\sigma^2 = 0.1$  and  $\beta = 1$ . Based on the posterior distribution obtained in the last question, draw four contour plots corresponding to  $p(\mathbf{a})$ ,  $p(\mathbf{a}|x_1, z_1)$ ,  $p(\mathbf{a}|x_1, z_1, \dots, x_5, z_5)$ , and  $p(\mathbf{a}|x_1, z_1, \dots, x_{100}, z_{100})$ . In all contour plots, the x-axis represents  $a_0$ , and the y-axis represents  $a_1$ . The range is set as  $[-1, 1] \times [-1, 1]$ . In each figure, also draw the true value of  $\mathbf{a}$ , which corresponds to the point  $(-0.1, -0.5)$ .
3. Suppose that there is a new input  $x$ , for which we want to predict the target value  $z$ . Write down the distribution of the prediction  $z$ , i.e.,  $p(z|x, x_1, z_1, \dots, x_N, z_N)$ .
4. Let  $\sigma^2 = 0.1$  and  $\beta = 1$ . Suppose that the set of the new inputs is  $\{-4, -3.8, -3.6, \dots, 0, \dots, 3.6, 3.8, 4\}$ . Plot three figures corresponding to the following three cases:
  - (a) The predictions are based on one training sample, i.e., based on  $p(z|x, x_1, z_1)$ .
  - (b) The predictions are based on 5 training samples, i.e., based on  $p(z|x, x_1, z_1, \dots, x_5, z_5)$ .
  - (c) The predictions are based on 100 training samples, i.e., based on  $p(z|x, x_1, z_1, \dots, x_{100}, z_{100})$ .

In all figures, the x-axis is the input, the y-axis is the target, and the range is set as  $[-4, 4] \times [-4, 4]$ . Each figure should contain three components: 1) the new inputs and the predicted targets; 2) a vertical interval at each predicted target, indicating the range within one standard deviation; 3) the training sample(s) that are used for the prediction. Use `plt.errorbar` for 1) and 2); use `plt.scatter` for 3).
